Re: **Report of Findings**

Insured Name:	Garden Grove Townhome
File Number:	5021107605-1
Date of Loss:	May 29, 2022
Address:	Garden Grove Townhomes - 38 Buildings With 96 Units Garden Grove Court, Garden Cress Court, & Brittany Drive Grand Junction, Colorado 81501

Dear Mr. Prudholm:

At your request, Knott Laboratory, LLC (Knott) inspected the properties located within the Garden Grove Townhome subdivision located in Grand Junction, Colorado. This report provides the findings and conclusions reached as a result of that investigation.

Background

The subject properties exhibited multi-family, wood-framed residences arranged in duplex- and triplex-type single-level structures. Records obtained from the Mesa County Assessor's Office indicate the structures were originally constructed between 2002 and 2006. There were (38) individual buildings housing approximately (96) total townhome units. A summary of the buildings, addresses, and dates of construction is included in **Appendix B**.

The exterior walls were clad with stucco and stone façades. The roofs were covered with asphalt composition shingles with fiber-reinforced base mats in laminate configurations (dimensional asphalt shingles). A review of a small sample of the (96) units via the Mesa County Building Department's permit database did not indicate any roofing-related permits. The structures were oriented in varying directions and exhibited gable-type or hip-type roofs exhibiting approximately 4:12 primary roof pitches. The (38) separate structures were located on Garden Grove Court, Brittany Drive, and Garden Cress Court. Knott labeled the various structures and herein refers to the structures by their labeled number for the remainder of the report, see **Figure 1.** A summary of the buildings, addresses, and date of construction is included in **Appendix B**.

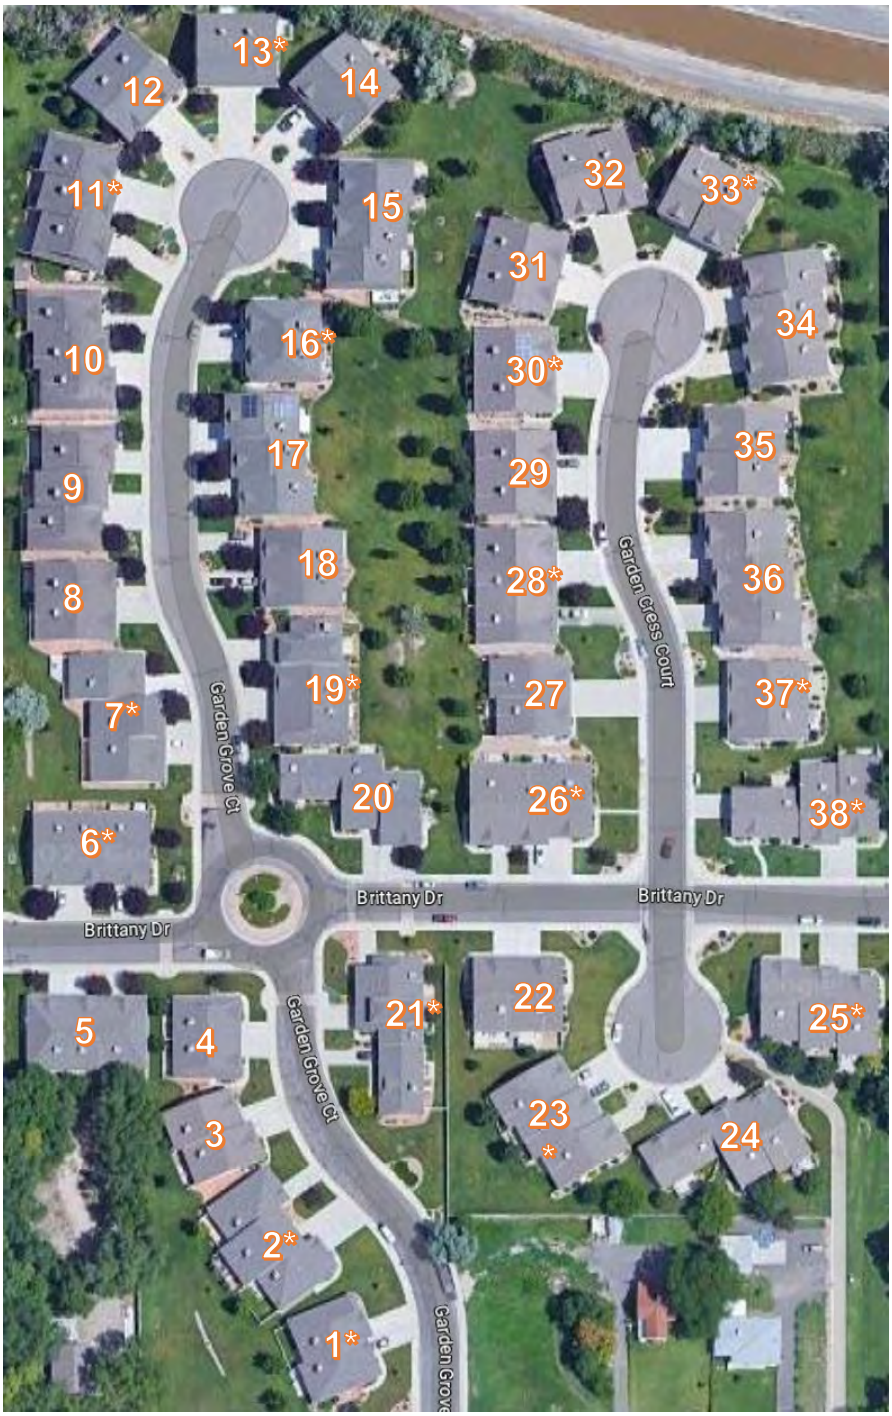

Figure 1 – Overview of Garden Grove Townhomes and associated building labels.

The following information was made available to this investigation: An insurance claim was submitted on January 27, 2023 in which hail damage was reportedly discovered while

investigating a unrelated water leak on a roof. The date of loss of the hail-related damage to the roofs was given as May 29, 2022. Additionally, there has also been wind-related damage reported to some of the buildings while recently observing the roofs.

Purpose

Knott Laboratory was retained by Farmers Insurance Exchange to inspect the subject properties and determine if the (38) buildings exhibit wind-related or hail-related damage and an approximate timeframe of said damage.

Procedure

Knott Laboratory inspected the subject structures on April 19, 2023 and April 24, 2023. Knott observed the neighborhood overall and observed all of the structures from ground level. Additionally, Knott conducted roof inspections on a specific selection of (17) of the structures. Knott chose specific structures based on their year of construction and the primary roof orientation to establish a sample set to encompass varied selection of all potential roof types and orientations (i.e. structures built in 2002 with a N/S roof orientation, structures built in 2002 with an E/W roof orientation, etc.). All of the structures were located within approximately a 600-foot radius and exhibited similar layouts, roof orientations, and roofing materials. Thus, inspecting a sample of all basic variations of roofs including year of construction and roof orientation establishes a pattern of damage which would be expected to occur on neighboring structures.

Knott's Samuel Henning, PE, Stanley Stoll, M.Eng., PE, and Taylor Valentine, B.Sc. conducted the inspection while Mr. David Estep of National Claims Negotiators, a public adjuster representing the HOA, was present. Knott documented and photographed the available information during the inspection. The photographs depicted in **Appendix A** are a sample of the photographs taken by Knott, and the remaining may be presented upon request.

Knott Laboratory did not review the insurance policy terms, limits, conditions, or coverages. The issue of insurance coverage is beyond the scope of this report.

Documents Reviewed

The following documents and materials were reviewed and/or referenced as part of Knott's investigation, and/or contain information pertinent to the discussion and conclusions presented herein:

Findings and Discussion

Knott has divided this section of the report into the following subsections for clarity: *Weather Data, Onsite Hail and Wind Indicators, Hail Damage Background, Hail Damage Evaluation, Wind Damage Background,* and *Wind Damage Evaluation*. All photographs referenced in the discussion are provided in **Appendix A.**

Weather Data

In conducting this investigation, Knott reviewed available hailstorm data from the Community Collaborative Rain, Hail and Snow Network (CoCoRaHS) from April 1, 2018 through April 12, 2023 in Mesa County, Colorado – approximately 5 years of data. In addition, Knott reviewed available hailstorm data for Mesa County from the National Oceanic and Atmospheric Administration's (NOAA) Storm Events Database (SED) from April 1, 2018 through December 31, 2022 (the latest available data), as well as the National Weather Service NWSchat Local Storm Report Application (NWSLSR) hailstorm data obtained from the Iowa State University Iowa Environmental Mesonet's Archived Local Storm Reports tool between January 1, 2023 and April 12, 2023.

Shown below in **Table 1**, the largest hail reported within 5 miles of the property during the researched period was 5/8-inch in diameter recorded on June 19, 2019, and was approximately 4.6 miles east of the subject properties. On the given date of loss of May 29, 2022 there were three stations which indicated hail between 3/8- to 1/2-inch in diameter located within three miles to the west and northeast of the properties. Of note, SED and NWSLSR did not show reports of hail within 5-miles during the researched timeframes.

Table 1 – Summary of hail data closest to the subject property during the researched time frame from the above-referenced sources.

Knott also reviewed available wind data from the NOAA CDO weather database from April 1, 2018 through April 12, 2023 in Mesa County, Colorado. The closest station to

record wind was located at Grand Junction Walker Field which is approximately 2 miles north of the subject properties. The daily maximum 5-second wind gusts and corresponding directionalities were recorded in the dataset. Knott truncated the large dataset to show only gusts over 60 mph, see **Figure 2.** The data indicated a maximum 5 second wind gust of 72.9 mph on April 26, 2019. The highest gusts were generally within the 60 mph range with the latest elevated gust of 69.1 mph recorded on March 22, 2023. The predominant wind directionality was generally out of the west for most data points (approximately 270-degree direction). For a general reference, design wind speeds for Mesa County is currently 115 mph (V_{ult}). See **Appendix C** for the full sets of weather data.

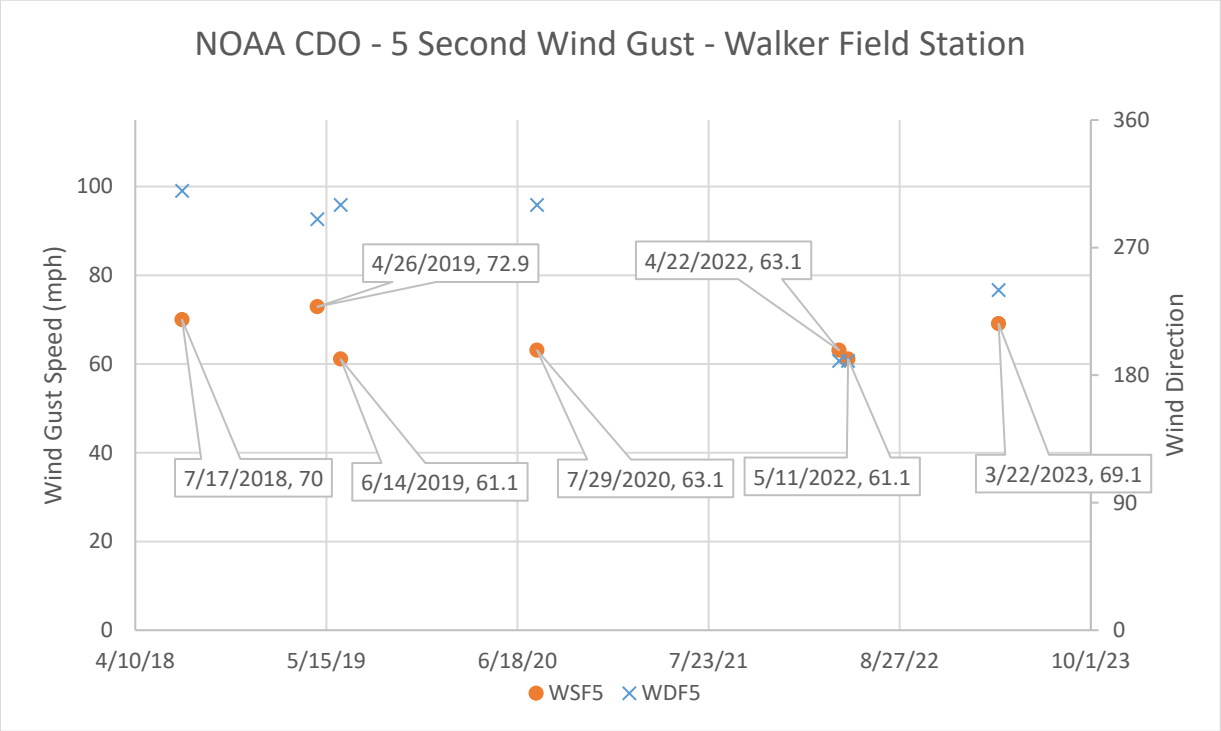

Figure 2 – NOAA CDO Wind Data. Gust speed and directionality.

Onsite Hail and Wind Indicators

Hail:

Knott inspected the roof and surrounding property of the subject residences for indications of exposure to hail. Exposure of a structure to a hailstorm typically results in dimple-like indentations in metal surfaces, roughly circular chips or abrasions in exposed wood surfaces, and spatter marks on various weathered, stained, or oxidized surfaces. Spatter marks are aesthetic blemishes commonly created by hailstone impacts and characterized by removal of dirt, microbial growth, and/or oxidization, from the material surface, which results in anomalies that vary in color relative to adjacent areas that were not impacted

by hail. Because spatter marks will fade over time due to microbial regrowth, reoxidation, or general weathering, the presence of such marks indicates the exposure of a property to relatively recent hail but does not in and of itself represent hail damage. The time it will take for spatter marks to fade is dependent upon numerous, usually unknown factors, but it has been Knott's experience that this process typically takes one to two years.

Knott's inspection of collateral surfaces on the roofs, building elevations, and surrounding property revealed the following:

- Spatter marks:
  - Up to 1/2-inch diameter on flat and west-facing surfaces of plastic mailboxes and oxidized metal surfaces (**Photographs 1 through 4**)
  - Up to 1/2-inch diameter on flat and west-facing rooftop RTU units (**Photograph 5**)
  - Up to 3/8-inch diameter on west-facing surfaces of vinyl fence surfaces (**Photograph 6**)
  - Up to 3/8-inch diameter on west-facing metal garage door surfaces (**Photograph 7**)
- Roughly circular clean spots/abrasions (wood surfaces):
  - None to wood fence (**Photograph 8**).
- Metal indentations:
  - HVAC condenser fins: up to 1/2-inch diameter on west-facing surfaces (**Photograph 9**).
  - Aluminum vents: up to 1/2-inch interior diameter (**Photograph 10**)
- Windows:
  - Minor chips to some west-facing window glazing beads – potential hail impacts (**Photograph 11**)
  - No marring or damage to window screens (**Photograph 12**).

The collateral indicators of hailstone impacts described above provided evidence of recent exposure to hailstones up to 1/2-inch in diameter, approaching from the west. Considering Knott's review of historical weather data, the evidence of up to 1/2-inch diameter hailstones onsite coincided with the given date of loss of May 29, 2022 in which up to 1/2-inch diameter hail was recorded, discussed above. This was also the largest hail diameter recorded in the dataset.

Wind:
Knott also inspected the roof and surrounding property for evidence of exposure to elevated wind speeds. Such evidence is commonly observed in the form of removed or displaced roof vent caps, or other light-weight appurtenances, particularly when loosely attached to the roof or building envelope. Such features are particularly vulnerable at the corners of the roof and building structure where the pressures created by wind are

typically the greatest. Other common indicators of elevated wind speeds include downed trees and large tree limbs.

During the investigation, Knott did not observe any downed trees or large tree limbs (**Photograph 12**). Knott also did not observe any displaced or missing rooftop or wall-mounted appurtenances, downspouts, or gutters which would be indicative of exposure to potentially damaging wind speeds.

Hail Damage Background

Hail damage to asphalt-composition shingle roofing is typically characterized by a widespread, random-distribution of roughly-circular blemishes, generally no smaller than 3/4-inch in diameter, which are characterized by missing granules, granules forced into the shingle mats, and a reduced cross-section (bruising) and/or fracturing of the shingle mats. Granule loss associated with hail damage often presents in a distinctive ring-shaped pattern with missing granules surrounding a central area of granules forced into the mat. Bruising of the shingle mat produces a weak spot that feels soft and pliable relative to the unaffected portions of the shingle and results in a slight depression of the affected area. Generally, granule loss unaccompanied by fractures or bruising of the shingle mat is not considered to constitute functional hail damage; asphalt shingles are designed as a weathering surface and granule loss is anticipated to occur naturally with age and as the result of normal weathering events including rain, snow, ice, wind, ultraviolet (UV) exposure, and small, otherwise non-damaging hail.

Recently exposed areas of shingle asphalt are expected to be black or dark gray in color and fade to dull gray over time due to weathering and exposure to UV radiation, which draws light oils out of bituminous materials. Extensively weathered areas of exposed asphalt may exhibit flaking or erosion and exposed fiberglass reinforcement. Information about the age of blemishes of all types can be gained by examining the condition and coloration of the exposed asphalt and/or fiberglass. Although the amount of time required for the asphalt to transition from dark gray or black to dull gray is variable and dependent upon numerous factors, it has been Knott's experience that this transition typically occurs over a period of approximately a year and the exposure of reinforcing fibers takes longer still. Hail damage is typically randomly located across the roof and slightly changes shape from one impact site to the next. Additionally, as hailstorms typically originate from one direction, one or two of the roofing faces will have more prevalent hail damage than the other faces. In this case, hail damage would be expected to be the most prevalent/worst on west-facing roof slopes given the directionality established based on the spatter mark locations throughout the neighborhood. Knott Laboratory inspected each roof slope for damage consistent with this criterion.

Hail-related damage is typically most-concentrated and severe along ridges, rakes, valleys and eaves where substrate support for the shingles is discontinuous. Through

laboratory testing by independent testing agencies and Knott, it has been established and commonly accepted that the minimum hailstone size expected to fracture or bruise well supported laminate, fiberglass reinforced asphalt-composition shingle roofing is 1.5-inches in diameter.

Knott has researched and performed engineering calculations to determine the amount of energy transferred to the roof tile as a result of a hail stone impact. Hailstones are pulled towards the ground by gravity at a constant acceleration rate of 32.2 feet per second squared. During their travel toward earth's surface, hailstones reach a speed wherein they no longer accelerate due to air resistance known as terminal velocity. A larger and heavier hailstone will accelerate to a higher velocity than a smaller hailstone. Once the terminal velocity has been calculated, the kinetic energy transferred on impact can be determined which is dependent on both the mass of the hailstone and the velocity. **Table 1**, below, summarizes the amount of energy transferred upon impact from hailstones ranging in size from 1/2-inch to 2½-inches in diameter. Relevant to this case, the impact energy calculations indicate that a 1/2-inch diameter hailstone (the maximum size of the hail observed at the subject properties) would have impacted with less than 2% the energy of a 1.5-inch diameter hailstone (the typical size of hailstone required to damage the asphalt laminate asphalt shingles).

Table 1 – Hailstone Impact Energy[1]

Hail Stone Diameter	Volume	Weight	Terminal Velocity	Impact Energy
Inches	in^3	lbs.	Mi./hr.	Ft-lbs.
1/2	0.07	0.002	39.5	0.12
3/4	0.22	0.008	42.3	0.51
1	0.52	0.018	49.8	1.59
1 1/4	1.02	0.035	55.9	3.72
1 1/2	1.77	0.060	61.4	7.88
1 3/4	2.81	0.095	66.2	14.91
2	4.19	0.142	71.6	26.56
2 1/4	5.96	0.203	76	43.51
2 1/2	8.18	0.278	79.8	67.86

Hail Damage Evaluation

Knott observed the shingles to consist of laminate, architectural shingles with fiberglass base mats on all structures. Presumably, the shingles were manufactured at various times given that the structures were constructed between 2002 and 2006. Thus, Knott inspected a wide selection of individual roofs to encompass predominant roof slope directionalities and the various years of construction as to include several specimens from each subset of combinations. Knott thoughtfully selected and inspected a total of (17) of the (38) roofs

[1] Hagg Engineering, Dallas, Texas.

which included Buildings 1, 2, 6, 7, 11, 13, 16, 19, 21, 23, 25, 26, 28, 30, 33, 37, and 38 These buildings are denoted in **Figure 1** with an asterisk *.

At the ridges, rakes, and eaves, no evidence of hail was observed to the asphalt shingles. Overall, the shingles at these locations were free from roughly circular blemishes and there was no impacted or missing granules consistent with hail-related exposure (**Photographs 14 to 18**). These particular areas would be expected to have manifested hail-related damage the worst given that they are relatively unsupported and more susceptible to hail damage.

In the field of the roof, no evidence of hail-related impacts were observed to the asphalt shingles. It would be expected that the west-facing roof slopes would likely have the most hail-related damage given the west-to-east hailstone trajectory established throughout the neighborhood. The west-facing slopes did not exhibit evidence of hail-related impacts nor did the north, south, or east facing slopes (**Photographs 19 to 23**). This is consistent with the significantly lesser impact energy of the small diameter (1/2-inch) hail stones.

In some isolated instances, there were roughly circular blemishes and missing granules as is common with many roofs as they weather and degrade. A circular blemish or missing granules in and of itself is not an indicator of hail damage. In the cases of missing granules or other forms of blemishes, Knott considered if there was sporadic instances or if it was just an isolated singular event. For instance, on Building 21 there was (1) location along a ridge cap with missing granules (**Photographs 24 and 25**). There was no bruising or fracturing coincident and there was no other blemishes along the entire ridge cap or sporadically across the roof and, as such, this isolated blemish was determined to not be hail-related. Additionally, the public adjuster pointed Knott to several examples of missing granules on the roof surfaces. Knott observed the isolated granule loss to be non-sporadic and non-circular in nature with no fractured or bruised mats; the blemishes were isolated instances of granule loss on the shingle unrelated to hail damage (**Photographs 26 and 27**).

Similarly, Knott observed a multitude of blemishes and tears on many of the roof surfaces. The tears and blemishes were non-sporadic and isolated instances consistent with mechanical damage to the roof. The tears also generally exhibited weathered edges with exposed fiberglass mats indicative of a historic issue and not a recent event (**Photographs 28 and 29**). Some areas of shingles exhibited granule loss and exposed fiberglass mats around the perimeter of the tabs which was inconsistent with hail-related damage and indicative of common granule loss at the perimeter of the tabs associated with common weathering (**Photograph 30**). At a small number of the buildings, there was widespread granule loss in horizontal strip-type patterns across the widths of the shingles. This type of linear granule loss was inconsistent with hail-related damage and indicative of some type of manufacturing deficiency in which the granules were more prone to de-

bond at certain linear regions of the shingles (**Photographs 31 and 32**). Overall, many of the buildings exhibited widespread granule loss – especially on the south facing roof slopes consistent with UV and heat degradation associated with the most sunlight exposure on south facing slopes (**Photographs 33 and 34**). Excessive degradation to south facing roof slopes over time is a common occurrence to asphalt shingles.

Overall, the roofs are weathering as would be expected given their age. Assuming the roofs are original to construction, the asphalt shingles are approximately 17- to 21-years old and are approaching the end of their useful lifespan. In some isolated instances, there is excessive granule loss and is likely related to an underlying manufacturer defect and unrelated to a recent weather event such as hail. No hail-related damage was observed to asphalt shingles on any of the (17) buildings observed. Likewise, the weather data and onsite hail indicators indicated 1/2-inch diameter hail was recently at the property which is well-below the known threshold required to damage asphalt composition shingles. As such, *Knott determined there was no recent hail-related damage to the subject asphalt composition shingles.*

Knott did observe hail damage to ancillary items on the structures. As discussed above, the predominant directionality of the recent hailstorm was in the easterly direction impacting western-facing surfaces. In this case, multiple rooftop mechanical units (aka RTUs) were located on each of the buildings. The RTU types and styles varied in type and orientation and the coil fins were exposed and oriented towards the west on some RTU units. As discussed above, 1/2-inch diameter indentations were observed in these coil fins facing west (**Photograph 9**). Knott observed all of the RTU throughout the (38) buildings for exposed coil fins in the westerly direction and associated indentations. Knott observed that (33) RTU units exhibited indentations to their coil fins located on a total of (16) buildings which was consistent with a recent hail event, see **Table 2**. Although indented, the coil fins are commonly ‘combed-out’ and straightened which repairs them without affecting the efficiency of the system. *Knott determined (33) RTU units’ coil fins were indented due to a recent hail event. Knott recommends the coil fin indentations can be combed-out and the RTU units do not require replacement.*

Building Number	Primary Roof Orientation	HVAC Fins	Building Number2	Primary Roof Orientation2	HVAC Fins
1	E/W	0	**20**	N/S	0
2	E/W	1	**21**	E/W	1

Table 2 – Summary of RTU Coil Fin Indentation Locations

Similar to the ancillary damage to the RTU coil fins, Knott observed that the vinyl window glazing beads were chipped along their lower edge in some instances. The windows were located on the western elevation of the buildings and chipping of the thin and brittle vinyl (i.e. PVC plastic) may occur with direct hail strikes (**Photographs 11, 35, and 36**). The directionality on the western window beads was consistent with the directionality of the recent hailstorm, as discussed above. Knott observed the approximate (156) total western-facing windows throughout the (38) buildings for hail-related damage to the vinyl window beads. Knott counted a total of (42) windows on a total of (23) buildings exhibited chipped window glazing beads, see **Table 3**. The chips were located on the bottom glazing bead which appeared to be snap-in type and removable from the window-frame as evidenced by some portions of beading which had previously become partially detached (**Photograph 37**). *Knott determined (42) windows exhibited chipped lower glazing beads due to a recent hail event. Knott recommends the lower glazing beads be removed and replaced; Knott anticipates just the vinyl glazing beads can be replaced without removal of the window glazing or window frame.*

Table 3 – Window Glazing Bead Chip Locations

Wind Damage Background

Wind damage to asphalt composition shingles typically manifests as torn or creased shingle tabs or groups of entirely missing shingles. While tears and creases can result from either a single elevated wind speed event or the cyclic “flapping” of unsealed shingle tabs during repeated exposures to lesser wind pressures, groups of entirely missing shingles are typically associated with isolated elevated wind speed events, which forcefully tear the shingles from the roof. Because of the lapped nature of shingles and the relatively uniform roof zone pressures created by wind, missing shingles caused by wind are also expected to manifest in groups; a single missing shingle in the field of a roof slope may be indicative of another cause of damage or a localized installation defect. Similarly, torn and creased shingles resulting from an isolated elevated wind speed event are expected to manifest in groups. If the damage resulted from a single straight-line wind event (most non-tornadic wind events), roof slopes facing one or two adjacent directions, which were windward during the event, are expected to exhibit the most extensive damage. Wind pressures acting on leeward slopes can also cause damage, but to a lesser extent. Isolated creased or torn shingles distributed relatively uniformly throughout roof facets facing more than two adjacent directions are typically the results of flapping

under pressures applied by repeated normal wind exposures. The cyclic flapping results in fatigue of the shingle mat and eventually creases/tears. Variably colored asphalt within crease and tear lines is also an indication that the damage has occurred over an extended period and is not associated with an isolated elevated wind speed event. Wind damage of all types is typically expected to manifest first and most predominantly at or near eaves, ridges, and rakes where wind pressures are higher than those experienced in the fields of the roof.

Wind-caused creases and tears typically manifest in a single, uniform horizontal line across the top of the exposed portion of a shingle tab; shingles with multiple creases/tears, diagonal or vertical creases/tears, jagged or non-uniform creases/tears, or creases/tears located lower on the shingle are generally not consistent with wind uplift pressures. Such issues are typically associated with man-made or mechanical damage, and in some cases can be caused by manufacturing defects. When manufacturing defects are the cause, uniform blemishes often occur in clusters or repeated patterns. Hip and ridge cap shingles are the exception; diagonal tears across the corners of cap shingles can be associated with wind uplift pressures.

Unsealed shingle tabs which are not otherwise physically damaged (creased/torn) are not considered to be functionally damaged. Unsealed tabs have a variety of causes including improper fastening, manufacturing defects, installation in cold temperatures, dirt/debris accumulation on the strips prior to sealing, and general ageing/weathering of the bituminous sealant strip material.

Wind Damage Evaluation

Knott's field investigation included a visual inspection of the fields of each roof facet and detailed inspections of the vulnerable roof ridges, eaves, and rakes at (17) of the buildings, as discussed above. In general, the shingles exhibited varying degrees of granule loss consistent with their age and orientation on the roof slope. The shingles were generally well-adhered at each course. Knott's inspection of the roof facets yielded the following wind observations summarized in **Table 4**:

Building Number	Built	Primary Roof Orientation	Wind Damage to Shingle?	# Shingles	Description
1	2002	E/W	No	0	NA
2	2002	E/W	No	0	NA
6	2003	N/S	No	0	NA
7	2004	E/W	Yes, historic	1	(1) torn applique tab near historic repairs
11	2004	E/W	Yes, historic	6	(5) torn applique tab only. (1) torn at ridge
13	2004	N/S	Yes, historic	3	(3) torn at ridge ends. Weathered tears
16	2003	E/W	No	0	NA
19	2003	E/W	No	0	NA
21	2002	E/W	Yes, historic	1	(1) torn at ridge. Weathered tear.
23	2005	E/W	No	0	NA
25	2006	N/S	No	0	NA
26	2006	N/S	No	0	NA
28	2005	E/W	Yes, historic	1	(1) applique missing. Weathered tear
30	2005	E/W	No	0	NA
33	2005	N/S	No	0	NA
37	2005	E/W	Yes, historic	3	(2) torn at ridge, (1) torn in field. Weathered tears.
38	2006	N/S	Yes, historic	2	(1) torn at ridge and (1) torn in field. Weathered

Table 4 – Wind Damage Summary Table

Of the (17) buildings observed, (9) buildings did not exhibit any wind-related damage whatsoever and the remaining (8) buildings exhibited minor wind-related damage. Overall, there were no completely missing shingles nor large groups of shingle damage. The damage was generally isolated and historic with discoloration and exposed fiberglass mats at the creases/tears. Many of the tabs which were torn/creased were re-adhered and had not been displaced from the roof. Common wind damage to the asphalt shingles included:

- Building 7: Historic wind-related repairs near the ridge with (1) additional torn/creased tab nearby. Tab exhibited weathered edges and discolored matt indicating historic damage (**Photographs 38 and 39**).
- Building 11: (5) torn applique tabs on the west slope. Torn appliques were historic with discolored edges and exposed fiberglass mats (**Photograph 40 and 41**). (1) historic tear at ridge cap with discoloration and exposed fiberglass matt.
- Building 13: (3) historic tears at the edges of ridge cap shingles (**Photograph 42**).
- Building 21: (1) historic crease at ridge cap shingle (**Photograph 43**)
- Building 28: (1) historic creased and missing applique tab (**Photograph 44**). (2) torn and re-adhered

- Building 37: (2) historic tear at ridge (**Photograph 45**), (1) historic tear in field (**Photograph 46**)
- Building 38: (1) historic tear in field (**Photograph 47**), (1) historic tear at ridge (**Photograph 48**).

Additionally, the public adjuster pointed Knott towards some anomalous tears located on a few of the buildings' roofs. The tears were observed to generally be diagonal or vertical and jagged. The tears did not correspond to any creases nor tears about the upper bend line which is typically associated with wind damage. At the tears, both sides of the tabs and the adjacent shingles were well-adhered which indicated they had either been repaired previously or had re-adhered themselves sometime after the tears occurred (**Photographs 49 through 54**). The tears exhibited exposed fiberglass mats consistent with historic tearing and were not located on any specific roof facet as to indicate a singular wind-event directionality. Overall, these types of tears were historic and inconsistent with wind-related pressures. These vertical and diagonal tears were most consistent with expansion and contraction of the underlying shingles, specifically given that they occurred concurrently at a seam in the underlying shingles.

Overall, there were no completely missing shingles or groups of shingles identified at any of the roof slopes. There were a relatively minimal amount of creased, torn, or missing applique tabs and ridge shingles. The characteristics at the torn edges of the shingles indicated historic wind-related damage. The overall lack of recent wind-related damage at the subject buildings also coincided with the lack of elevated wind gusts as shown in the weather data as well. As such, *Knott determined there was no recent wind-related damage to the subject asphalt composition shingles.*

Conclusions

Based upon Knott Laboratory's inspection, the available information, and these engineers' education, training, and experience, the following conclusions have been reached within a reasonable degree of engineering certainty:

- Knott determined:
  - there was no recent hail-related damage to the subject asphalt composition shingles.
  - (33) RTU units' coil fins were indented due to a recent hail event. Knott recommends the coil fin indentations can be combed-out and the RTU units do not require replacement.
  - (42) windows exhibited chipped lower glazing beads due to a recent hail event. Knott recommends the lower glazing beads be removed and replaced; Knott anticipates just the vinyl glazing beads can be replaced without removal of the window glazing or window frame.
- Knott determined:

- there was no recent wind-related damage to the subject asphalt composition shingles.

Closure

The opinions and findings expressed in this report are based upon the information available to these writers as of the date of this report and are the result of limited non-destructive visual inspections of the exposed building components. As such, Knott Laboratory reserves the right to modify the conclusions contained herein upon receipt or discovery of additional information. Due to the limited access and the non-destructive nature of the investigation, Knott Laboratory cannot be held responsible for any hidden defects that may negatively impact the performance of the structures. This report is intended to provide an overview of the existing conditions and should not be used as an indicator of future performance; no expressed or implied warranties or guarantees of any kind are given.

Respectfully submitted,

Appendix C: Weather Data

Weather records were obtained from multiple sources during the course of this investigation. Knott Laboratory obtained and filtered available weather records from the time frame as described in this report. No changes were made to obtained datasets that would alter factual representations or the opinions and findings expressed in this report.
